Abstract

Global warming has been proved to be caused by the excessive emissions of CO₂ from the usage of fossil fuels. Therefore, promoting carbon mitigation strategies and energy transition are of increasing importance. Reduction of CO₂ to C₁ fuels by solar energy like artificial photosynthesis is thus environmentally attractive and close the carbon cycle. There are still major challenges such as low conversion efficiency and high recombination of electron-holes during photocatalytic reduction of CO₂. We have developed novel perovskite quantum dots (PQDs) encapsulated within metal organic frameworks (MOFs) (PQD@MOF) composite for dual photoelectrodes to proceed the high-efficiency photocatalytic reduction of CO₂. By the PQD@MOF under visible-light irradiation, about 500 μmol C₁/mgCat/h were obtained. It is apparent that the novel PQD@MOF photocatalysts are chemically feasible for solar-driven CO₂ reduction to C₁ fuels.

Keywords: photocatalytic reduction of CO₂, perovskite, metal organic frameworks, reactor design
